

Lecture 9

File Handling Questions

Q1. When you don't know in advance how many values are there in a file but a maximum limit is known (let's say maximum of 50 values can be in the file given below). Let's write a function to read such kinds of files.

Input.txt

```
45 89 78 65 34 67 32 78 90 54 23 56 87 65  
12 45 67 32 21 67 89 92
```

Q2. An input file contains the data in the following format. Create a function in C++ to read first number in integer variable, operator in a char variable and second number in a second integer variable and use suitable selection statement (if /if-else/ if-else if) to perform the desired operation based on the operator read .

Stored the result of each operation in an output file in separate lines

Input.txt

```
12+24  
12-24  
12*24  
24/12
```

output.txt

```
36  
-12  
288  
2
```

Q3. An input file contains n number of integer values separated by space. The first line of file will tell number of inputs in a file to read. Create an array of maximum size of 20 to read n ($n \geq 1$ & $n \leq 20$) input from user.

Now create a function to read all the n values from user in that array.

Create a function to write all the odd values (if any) read in that array in a separate file odd.txt

Input.txt

```
n=5  
12 56 89 76 45
```

odd.txt

```
89 45
```

Q4. Write a Function in C++ that count total lines in a file.

Q5. Write a function in C++ that counts total words in a file.

Q6. Write a function to count remove all the blank spaces from the given input file containing multiple lines of text.
